

Data Flows

Data flow is mainly used for pega marketing, and it contain lot of in-built configurations to optimize the performance during the execution.

Data Flow Types

- ★ Batch Processing
- ★ Real-Time-Processing
- ★ Single Case Processing

Batch Processing:

- ◆ Batch data flows are mainly used for processing large volumes of data
- ◆ It can be created instance class as PEGA-DM-DDF-WORK
- ◆ If we can run data flow at least one node is up and running
- ◆ It can be invoked internally using **Dataflow-Execute** method

Real-time processing:

- ◆ Real-time data flows are always active and continue to process incoming stream data and requests.
- ◆ It can be invoked based on real time event that can be happen in system

Single Case Processing

Single-case data flows are run on request, with the data flow source set to abstract. Single-case data flows are mostly used to process inbound data.

Data Flow Shapes

Compose Shape: Used to combine the data from 2-different sources (only matching data) and stored into Page List / Page

Convert: Used to change the context of result (Present data is available is Customer class then change to Accounts class)

Filter Shape: Filter the result based on condition

OOTB Data Flow: Single Customer Data Flow

Q. How to identify which is Batch data flow and real time data flow, without running data flows?

Based on source we can identify the data flows. If the source is Stream Service / kafka then we can call it as Real time data flow.

If the source is other than stream and kafka, we can call it as Batch data flow.
